'Deeper' distributional semantics

- Can we do linguistic analysis using distributions?
- Can we improve DELPH-IN tools and resources in the process?

- 4 ∃ →

Outline

Introduction

Producing distributions from the ERG

- The semantics of adjectives
 - Adjective types
 - Obtaining adjective types from distributions
- 4 The semantics of quantifiers

5 Conclusion

The corpus

wikiwoods, converted into DMRS format...

• ... and further processed to get 'lemmatised' links.

```
<node nodeid='10011' cfrom='28' cto='36'><realpred lemma='original' pos='a' sense='1'/>
<sortinfo cvarsort='e' sf='prop' tense='untensed' mood='indicative'/></node>
<node nodeid='10012' cfrom='39' cto='46'><realpred lemma='drummer/nn' pos='u' sense='unknown'/>
<sortinfo cvarsort='x' perse'3' num='sg'/></node>
<link from='10011' to='10012'><rargname>ARGI</rargname><post>EQ</post></link>
```

Pre-processing

- Nominalisations
- Compounds: fish compound_rel knife becomes fish_knife
- Coordination: precision issue, we don't know which predicates are distributive and which are collective.

Which relations?

- Adjective + noun
- Intransitive verb + subject
- Transitive verb + subject/object
- Ditransitive verb + subject/object 1/object 2
- Adverb + verb
- Adverb + adjective
- Preposition + ARG1 (noun)/ARG2
- Preposition + ARG1 (verb, with dependents)/ARG2
- Poss_rel + ARG1/ARG2
- Coordination + ARG1/ARG2

- 3 ≥ >

Example: language

Problem

- Due to the weighting function (PMI), parts of fixed expressions and named entities are high up in the distribution.
- The cases related to named entities could be easily weeded out if named entity tagging was provided in the ERG parse.

Outline

Introduction

The semantics of adjectives

- Adjective types
- Obtaining adjective types from distributions
- 4 The semantics of quantifiers

5 Conclusion

Adjective types, Partee (1995)

- Intersective: carnivorous mammal ||carnivorous mammal|| = ||carnivorous|| ∩ ||mammal|
- Subsective: skilful surgeon
 ||skilful surgeon|| ⊆ ||surgeon||
- Non-subsective: former senator
 ||former senator|| ≠ ||former||∩ ||senator||
 ||former senator|| ⊈ ||senator||

4 E b

▲ 同 ▶ → 三 ▶

Integrating adjective types in the ERG

- The MRS of *skilful surgeon* shouldn't be I1:skilful(x) I2:surgeon(x)
 - ... because x is not 'overall' skilful.
- Similarly, the current MRSs for *former*, *fake*, etc. are semantically inappropriate.

< 6 b

∃ >

Skilful

イロト イヨト イヨト イヨト

Extra complication

- The semantics of big city should definitely be 11:big(x)I2:city(x)
 - ... but lexically, there is more going on.
- Distributional intersective composition misses out on: loud, underground, advertisement, crowd, Phantom of the Opera...

- < ∃ →

Spotting non-intersective adjectives

- Hypothesis: the distributional meaning of non-intersective adjectives is not found in the phrases they appear in.
- That is... the cosine between skilful+surgeon^o and skilful^o should be fairly low.

▲ 同 ▶ → 三 ▶

Adjective distributions

- The nouns in ARG1 position?
- But then... no way to compare the distribution of the adjective with the distribution of an adjectival phrase.
- Instead: first assume all adjectives are intersective. Their semantic context is the semantic context of the nouns they modify.

→ ∃ →

Trying it out

- Looking at the 20 most frequent adjectives which occur with at least 10 different phrases of frequency >100.
- We record the average cosine between the adjective and the phrases it occurs in.
- Results:
 - .21287 late_a .20550 old_a .20047 large_a .19687 former_a .19649 original_a .19338 early_a .18843 small_a .18591 only_a .18134 national_a .18046 general_a

イロン イロン イヨン イヨン

Clustering different adjective behaviours

- Does the behaviour of adjectives differ depending on the type of noun they modify?
- For each adjective, we cluster the nouns it modifies using three features:
 - The distance of the adjective's distribution to the phrase's distribution
 - The distance of the modified noun to the phrase's distribution
 - The distance of the adjective to the noun (distributions that are close indicate a high frequency of cooccurrence).

First thoughts

- Don't talk about intersective versus subsective/privative adjectives, but about intersective/subsective/privative *uses* of adjectives.
- Identify (semi-)fixed phrases (high school, high level): should be single lexical items??
- Adjectives with (mostly) flat distribution in the 'difference' space are *not* intersective.
- Low cosines between AN, A and N indicate anomaly in the semantics of an adjective (??)

< (17) ×

Outline

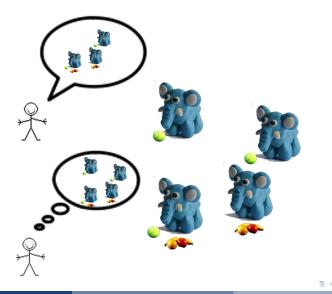

Introduction

- 2 Producing distributions from the ERG
- 3 The semantics of adjectives
 - Adjective types
 - Obtaining adjective types from distributions

The semantics of quantifiers

5 Conclusion

Counting with distributions

Herbelot (Universität Potsdam)

Quantification and LC

- Because LC is entirely compatible with model-theoretic semantics, we can quantify in the usual way...
- ... and do more...

The heffalump

Heffalumps eat grass. They are striped and have a long tail, as well as a trunk.

True or false: All heffalumps are animals. Most heffalumps live underwater. Some heffalumps are blind. All heffalumps are blind.

- Impossible to calculate probabilities... this cannot be treated in a pure model-theoretic setting.
- But we have lexical information. This let us resolve cases of underspecified quantification like *Heffalumps live in forests*. (Some, most or all?)

Outline

- The semantics of adjectives
 - Adjective types
 - ۲
- The semantics of quantifiers

Conclusion

 → 4 A N

• We can get nice distributions out of wikiwoods.

- It may be worth investigating 'deeper' lexical semantics issues under the microscope of distributions.
- Classical problems like quantification have the potential of being resolved beyond the level of models and truth.
- One day... integrate correct representations for adjectives in our grammars.
- Disambiguate quantification in the parse?
