

# Towards efficient HPSG generation for German, a non-configurational language

Berthold Crysmann<sup>1</sup> & Woodley Packard<sup>2</sup>

<sup>1</sup>CNRS, Laboratoire de linguistique formelle, Paris-Diderot    <sup>2</sup>University of Washington

24<sup>th</sup> International Conference on Computational Linguistics (Coling 2012)  
Mumbai, India, 10–14 December 2012

## HPSG bottom-up generation and non-configurationality

- ▶ Techniques used to solve generation efficiency for English HPSG (ambiguity packing and index filtering; Carroll and Oepen, 2000) insufficient to tackle efficiency issues with GG, an HPSG for German
- ▶ Combinatorial explosion already for relatively short utterances
- ▶ Inefficiency of HPSG generation for German result of several conspiring factors, all relating to non-configurationality:
  - ▶ Relatively free word order (in clausal domain): late packing
    - ▶ permutation of complements
    - ▶ interspersal of modifiers
  - ▶ Verb placement
    - ▶ Alternation between V1/V2 and verb final clauses: bottom-up search must explore both left-branching and right-branching hypotheses
    - ▶ Initial placement gives rise to discontinuous lexical items (particle verbs)
  - ▶ Argument composition
    - ▶ Complex predicates form verb cluster, permitting interleaving of arguments
    - ▶ Verb movement may separate highest verb from cluster
  - ▶ Rich inflection

## MRS term rewriting for generation efficiency

- ▶ Globally uninformed search with standard semantic input representation (MRS; Copestake et al., 2005) characterised by massive local ambiguity
- ▶ Large chunks of globally unsuccessful hypotheses can in principle be detected based on properties of the semantic input
- ▶ Information relevant for more informed search is only implicitly represented in the input
  - ▶ Information is out-of-place:
    - ⇒ needs to be redundantly encoded locally on elementary predications
  - ▶ Information is represented by structural configurations in the input:
    - ⇒ needs to be transformed into syntactic constraints
- ▶ Approach: Deterministically enrich semantic input with explicit syntacto-semantic constraints, suitable to early pruning of globally unsuccessful hypotheses

## MRS enrichment

Figure: Enriched input MRS for *Du sollst schnarchen* ‘You should snore’

## Enriching input semantics: Case

- ▶ Morphosyntactic case not represented in MRS input semantics (contrary to LFG f-structures)
- ▶ Baseline system therefore inflects every nominal expression (determiner, adjective, noun, pronoun) for all 4 possible cases  
Illicit case forms often detected very late during generation, because, with argument composition, case properties of inherited complements are locally unknown
- ▶ Case as a selected property can be derived from predicate-argument structure using linking information
- ▶ Case prediction must anticipate deviation from lexical case marking patterns
  - ▶ voice alternation (foregrounded role represented in semantics)
  - ▶ subject to object raising
  - ▶ conflicting case assignments in relativisation (exempted)
- ▶ Transfer grammar uses 35 rules to predict case of arguments

## Enriching input semantics: Punctuation

- ▶ Punctuation in GG (Kilian, 2007) attached to words by inflectional rules
- ▶ Host word for sentence-final punctuation can only be determined after generation:  
(almost) every chart item inflected in 5 different ways (none, comma, period, exclamation and question mark)
- ▶ Sentence mode, however, represented in input MRS
- ▶ Distribute information about matrix sentence mode onto all EPs
- ▶ Restrict inflection rules (period, exclamation mark, question mark) to appropriate sentence mode

## Enriching input semantics: Verb placement (SUB)

- ▶ German nonfinite verbs are final
- ▶ German finite verbs show placement alternation between initial (V1/V2) and final position
  - ▶ Final: relative clauses, embedded interrogatives, subclauses introduced by complementiser or subordinating conjunction
  - ▶ Initial: elsewhere
  - ▶ Initial/final word order can be detected from semantics, using
    - ▶ Sentence mode (declarative/interrogative)
    - ▶ Type of embedding (relativisation, complementation, conjunction)
    - ▶ presence of a topicalised element (embedded V2 vs. that-clause)
- ▶ Transfer grammar establishes for each verb “subordinate” vs. “non-subordinate” clause type
  - ▶ Predicts direction of branching for finite clauses
  - ▶ Predicts presence/absence of costly verb movement

## Enriching input semantics: Complex predicates

- ▶ Auxiliaries, modals, raising and control verbs form clusters
- ▶ Arguments of predicates in a cluster can be interleaved

*Letzte Woche versprach ein Buch er ihm zu kaufen*  
last week promised a book he him to buy

- ▶ Strong interaction with verb placement
  - ▶ Parser/Generator may encounter arguments of the initial verb, before knowing that verb's argument structure
  - ▶ Verb movement rules locally hypothesise additional dependents (subject and possibly object) whose identity is not known
  - ▶ Massive local ambiguity: **any** XP in the chart can satisfy hypothesised valencies
- ▶ MRS enrichment:
  - ▶ COH: restrict hypothesised valency to arguments of verb clusters
  - ▶ OIND: establish presence and identity of upstairs object
  - ▶ SIND: determine agreement for modals and raising verbs

## Enriching input semantics: Extraction

- ▶ Long-distance dependencies are notorious source for inefficiency
- ▶ Extraction in German very common (including ordinary declaratives)
- ▶ External MRS marks topicalised element as information structural property of propositions and questions
- ▶ Gap prediction for argument extraction (TOP)
  - ▶ Redundantly mark the inherent variable of topicalised EP as [TOP +]
  - ▶ Mark all other inherent variables as [TOP -]
  - ▶ Exempt realitivated EPs ([TOP *na*]), as they are extracted within the relative clause, but may be in situ outside
  - ▶ Restrict extraction rules to *na\_or\_+* and head-valence rules to *na\_or\_-*
- ▶ Gap prediction for adjuncts (TPC)
  - ▶ Adjuncts not represented on argument structure of the modified head
  - ▶ Use semantic attachment information in the input to identify extraction site

# Evaluation

- ▶ ACE generator
  - ▶ Open source runtime system for HPSG: parsing/generation/transfer
  - ▶ Implemented in C by Woodley Packard
  - ▶ Bottom-up chart generation similar to the LKB
  - ▶ Generation efficiency measures: ambiguity packing, index accessibility filtering (Carroll and Oepen, 2000)
  - ▶ Highly efficient: 14.7 times faster than LKB, 0.43s (vs. 6.34s) on Rondane treebank
- ▶ Test suites
  - ▶ 3 regression test suites for German (Babel, TSNLP, MRS)  
no test suite specifically designed for generation
    - ▶ Test items: 2259 total (MRS: 103, TSNLP: 1547, Babel: 609)
    - ▶ Avg. string length: MRS: 4.44, TSNLP: 4.76, Babel: 6.76
  - ▶ Automatically parsed and manually disambiguated with Redwoods
  - ▶ Generation from gold standard MRS semantics
- ▶ Test parameters
  - ▶ All performance features tested in isolation and in combination
    - +FEAT: compare individual feature to baseline performance
    - FEAT: assess feature's effectiveness in combination (leave one out)

## Main Results

- ▶ Combined effect of all efficiency measures yields significant performance improvement
  - ▶ speedup factor around 4.5 for MRS/TSNLP
  - ▶ speedup factor of 27.79 for Babel
- ▶ Space consumption reflects speedup, although savings are lower, owing to ambiguity packing (packed edges only counted once)
- ▶ Most features effective both in isolation and in combination

## Detailed results: Inflection features (*punct,cas*)

- ▶ Both inflection features consistently effective in isolation and combination
- ▶ PUNCT outperforms case prediction

Explanations:

- ▶ Punctuation prediction
  - ▶ is simple and exceptionless (5 rules)
  - ▶ applies to every part-of-speech (i.e. every lexical chart entry)
- ▶ Case prediction
  - ▶ Complex and large rule set (35 rules)
  - ▶ Many cases of exemption (e.g. relatives)
  - ▶ only applies to nominal expressions

## Detailed results: verb placement and argument composition

- ▶ Control for verb placement (SUB) beneficial throughout: controls both direction of branching and costly verb movement
- ▶ Control for argument composition and initial verb's argument (*oind*) more dependent on input complexity (when used in combination)
- ▶ *sind* (agreement on raising and modal verbs) far too item-specific

## Detailed results: Extraction features (TOP / TPC)

- ▶ Extraction features consistently improve performance on all test suites
- ▶ Features for extracted arguments (TOP) and extraction site (TPC) complementary
  - ▶ TOP targets argument extraction, while TPC targets adjunct extraction
  - ▶ both features still contribute massively when used in combination
- ▶ TPC constitutes best overall single feature

- ▶ Grammar-side efficiency features compare well to generator efficiency measures like packing and index filtering

## Discussion: scalability

- ▶ Difference in strength of cumulative effect (factor 5.5) between less (MRS/TSNLP) vs. more (Babel) complex test suites
  - ▶ Differences strongly correlate with input length
- Artificial reduction of string length of Babel to that of TSNLP (between 4.37 and 4.85) reduces difference to a factor between 1.2 and 2.1
- ⇒ Ceiling effect for less complex test suites
  - ⇒ Method effectively contains exponential growth problem

Figure: Processing time (in s) per string length (babel)

## Discussion: scalability

- ▶ Difference in strength of cumulative effect (factor 5.5) between less (MRS/TSNLP) vs. more (Babel) complex test suites
- ▶ Differences strongly correlate with input length

Artificial reduction of string length of Babel to that of TSNLP (between 4.37 and 4.85) reduces difference to a factor between 1.2 and 2.1

⇒ Ceiling effect for less complex test suites

⇒ Method effectively contains exponential growth problem

Figure: Passive edges per string length (babel)

## Discussion: portability

- ▶ Deterministic enrichment of input semantics effective in closing performance gap between non-configurational German and configurational English
- ▶ Some features clearly language dependent: e.g., *SUB* and *oind*, which are restricted to V2 languages like German and Dutch
- ▶ Most features applicable to a wider range of languages
  - ▶ Extraction features
    - Applicable to all languages with overt wh-movement or topicalisation
  - ▶ Case feature
    - Applicable, inter alia, to Slavic languages
  - ▶ Punctuation feature
    - ▶ Most widely applicable
    - ▶ Tests with English Resource Grammar (Copestake and Flickinger, 2000) on Rondane test suite yield 10.5% reduction in processing time

## Related work

- ▶ French SemFTAG (Gardent and Kow, 2007)
  - ▶ Enrichment of semantic generator input with tree features
  - ▶ Nearly deterministic paraphrase selection
- ▶ LFG (Zarrieß and Kuhn, 2010)
  - ▶ Transfer of syntactic f-structures to more general semantic representation
  - ▶ Inverse transfer step for argument structure to grammatical functions
  - ▶ Massive difference in generator performance as to the detail of the rules (between 36.2s and 246.14s per item)
  - ▶ Major difference:  
Semantic input readily accepted by GG, enrichment is a pure performance measure
- ▶ EnJu HPSG (Nakanishi et al., 2005)
  - ▶ Beam search approach for generation efficiency with tree bank-induced HPSG for English
  - ▶ Methods highly complementary:
    - ▶ Probabilistic pruning good at local decisions, e.g. for permutation of arguments
    - ▶ MRS-based enrichment permits non-local pruning with certainty
    - ▶ Combined system may yield good results at smaller beam sizes

## Conclusion

- ▶ Rule-based method to improve generation efficiency with GG, an HPSG for German
  - ▶ Deterministic enrichment of semantic input with syntactic constraints
  - ▶ Grammar-side pruning on the basis of enriched input
- ▶ Evaluation on three different test suites demonstrates significant speedup factors
  - ▶ around a factor of 4.5 for relatively short utterances up to almost 28 for slightly more complex inputs
  - ▶ performance gains increase with input length
- ▶ Grammar-internal enrichment successfully attacks exponential growth problem while maintaining a general semantic interface for application development

# ACE generator

## ▶ Overview

- ▶ Runtime system for HPSG: parsing/generation/transfer
- ▶ Implemented in C by Woodley Packard
- ▶ Open source since 2011: <http://sweaglesw.org/linguistics/ace/>
- ▶ Highly efficient: 14.7 times faster than LKB, 0.43s (vs. 6.34s) on Rondane treebank

## ▶ Bottom-up chart generation in ACE

- ▶ Generation algorithm similar to the LKB, including efficiency measures like ambiguity packing and index accessibility filtering (Carroll and Oepen, 2000)
- ▶ Reentrancies in the input made explicit by Skolem constants
- ▶ Chart initialised with
  - ▶ lexical items whose semantics unifies with some elementary predication(s) in the input
  - ▶ semantically empty lexical items introduced by special trigger rules
- ▶ Bottom-up creation of packed forest
- ▶ Selective unpacking (using realisation model) and linearisation
- ▶ Post-generation equivalence test (completeness)

## Term rewrite system

- ▶ LKB and ACE feature an MRS term rewrite system, originally developed for semantic transfer in MT (Oepen et al., 2004, 2007)
- ▶ Transfer grammars are sequential resource-sensitive sets of rewrite rules
- ▶ Rewrite rules are tuples  $\langle I, O, C, F \rangle$  consisting of *Input*, *Output* and *Context* descriptions, as well as a *filter* condition:  
Replace input  $I$  with output  $O$  in context  $C$ , provided that the filter  $F$  does not match
- ▶ Each of the patterns in  $I$ ,  $O$ ,  $C$  and  $F$  may specify an arbitrary number of elementary predications
- ▶ Complexity and efficiency
  - ▶ Due to resource-sensitivity, order may be significant for multiple matches of the same rule, giving factorial worst-case complexity
  - ▶ MRS enrichment should not introduce ambiguity, so processing is deterministic, using first path only
  - ▶ Transfer costs are relatively small:  
Abs: 13.2ms (MRS); 12.1ms (TSNLP) and 29ms (Babel)  
Rel: 24.4% (MRS), 19.2% (TSNLP) and 11.3% (Babel) of overall processing time with full transfer grammar
